

Assignment 2 - Applied Programming Concepts

Waterfall Model: Week 1 Through 5

1. Step one would be to create the classes and objects for the program and make sure all of their basic methods work when called and are properly inherited.
2. Then we would create the database to store course names, locations, instructor info, and student info.
3. Next we would make sure that we could access the information from the database to be used in the rest of the program.
4. Then we would finish up the more involved methods such as adding and dropping courses, printing classlists, printing schedules, etc.
5. Lastly we would make sure that all criteria are met and displayed in a neat and effective way.

Incremental Development Model: Week 1 Through 4

1. A good starting point would be to create the database and the classes and objects. No methods yet or bringing the database into the main program yet.
2. Next we would start with the more basic methods for the functions as well as bringing in the database. We would make sure we can call the basic functions and bring in info from the database.
3. Then we will work on the more involved methods and make sure those function to print schedules and classlists, as well as add and drop courses.
4. Lastly we will clean everything up and make it look nice and neat.

Integrate and Configure Model:

We could take inspiration and methodology from a system that is similar to the one we want to program. For example, the PeopleSoft Student Information System, or SIS, is a system used by students, instructors, and administrators to perform a variety of functions. Students can use SIS for scheduling classes, class registration, and student planners. Instructors can use SIS for an online class roster, and online grade submission.

We could integrate the parts of SIS for scheduling classes, class registration, and showing the class roster into our program to help us satisfy those requirements.
